

Round I - Solution Framework | Problem Statements

Artificial intelligence has moved from experimentation to the core of how modern enterprises operate — reshaping revenue streams, automating and augmenting everyday processes, and sharpening the speed and quality of business decisions across every function and industry. Organizations that once treated AI as a side initiative now build it into how they sell, serve, manufacture, and manage risk, and the businesses pulling ahead are the ones treating AI as a fundamental capability rather than a one-off tool.

This shift shows no sign of slowing, as AI models grow more capable and more deeply embedded into enterprise systems, they will continue to redefine what's possible across industries for years to come — ***making the ability to responsibly design, deploy, and scale AI one of the defining business skills of this decade.***

What do you need to do?

Through this competition, we're looking for bold, practical ideas that show how AI can reinvent the way businesses operate. This is your opportunity to think like an innovator. Choose one of the four business challenges and propose how AI could create meaningful impact. Tell us how your idea would work, who it would help, and why it matters. You don't need a fully developed solution yet; we're looking for creativity, practicality, and fresh thinking.

Problem Statements

1. ControlPlane.ai — Every AI deployment carries the same risk: it can be confidently wrong, quietly expensive, or subtly biased — usually discovered only after a user has already acted on it. ControlPlane Checker is a technology layer that continuously observes every AI response in real time across three dimensions: performance (right or confidently wrong), cost (burning more compute or rework than it should), and responsibility (biased, unsafe, or leaking data). Built to sit on top of any model, it turns AI

oversight from an after-the-fact discovery into something you can watch, catch, and act on live. That's the difference between finding out and finding it first.

Think about: How would you detect each risk category? Should a flagged response be blocked, edited, or escalated to a human — and how do you avoid slowing the AI down so much it defeats the purpose?

2. PatientTriage.ai — When a hospital emergency department is overwhelmed, patient sequencing depends heavily on one nurse's judgment under pressure — and mis-prioritization can cost lives. Design a patient triage assistant: an AI-powered decision-support tool that helps hospital staff prioritize and route patients as they arrive, reducing waiting times without replacing clinical judgment.

Think about: What should the assistant decide versus merely recommend? What data would realistically be available in the first few minutes of arrival, and how do you design for the worst case rather than the average one?

3. BusinessIntelligence.ai — A dashboard can show revenue dropped 8% in a region; it rarely explains why or what to do next — that translation still falls to an analyst, often taking days. Design a KPI storytelling engine: an AI system that explains in natural language what changed in a business metric, identifies likely root causes, and recommends next steps. It should use both structured and unstructured data.

Think about: *How would the engine separate meaningful change from normal noise? How does it move from correlation to something a business leader can act on — and what does it do when the data is genuinely ambiguous?*

4. DigitalTwin.ai — On a vehicle assembly line, a bottleneck at one station ripples downstream, and an early defect may go uncaught for dozens of vehicles. Design a digital twin prototype of a vehicle assembly line: a live, data-driven virtual model that helps plant teams see where bottlenecks are forming and predict likely defects before they happen.

Think about: *What does the twin need to model to be useful, versus what can it skip? How does it move from visualizing the line to predicting problems — and what do you do about stations with little or no sensor data?*

Deliverables:

- **Concept Deck:** Pitch deck (Max 3 slides) per team, covering your chosen problem statement, your concept/approach, and why it matters.
- **A video:** Short video (max 3 mins) to explain your idea and approach.

This brief is intentionally open — research, debate, and creativity are encouraged over technical precision at this stage.

Round 2: Shortlisted teams will gain access to deeper problem-domain insights and use them to evolve their ideas into detailed, prototype-ready solutions.
